A branch is a local copy of the repository. It usually means a new feature, bug fix or other change. It does not have any connection to a remote repository, so it is a local copy and can be merged to master, or any branch. It can be a master branch that is always there and is never merged with master. As you see, it is a local copy. You can do anything you want to it. That's why it is called branch. You can create different branches in your local copy of the repository. Git is an distributed version control system. It means that everything is always distributed and you have no central repository (with the master branch for example). You could work on a feature branch, but it is not associated with a remote, so you can just keep your local copy. In the original version control systems (P4, RCS), there was a central repository (with central version control), but you had to sync the repository. You can merge them, delete them, merge the master branch with the feature branch. The concept of merge is really important here. Merging is the process of combining the changes done to the branches (here, branches are the feature and the master branch). It can be done to keep the feature branch in sync with master, or to keep master in sync with feature. The question is: what version control system should you use? There is no answer, it depends on your needs and preferences. Git

(and GitHub for example) Mercurial TortoiseHg Bazaar Other systems like git-flow or Subversion are also possible. You
